Next.js (/app)

Getting started with Speed Insights

Ask AI about this page

Last updated September 24, 2025

This guide will help you get started with using Vercel Speed Insights on your project, showing you how to enable it, add the package to your project, deploy your app to Vercel, and view your data in the dashboard.

Speed Insights is available on all plans

To view instructions on using the Vercel Speed Insights in your project for your framework, use the **Choose a framework** dropdown on the right (at the bottom in mobile view).

Prerequisites

- A Vercel account. If you don't have one, you can sign up for free.
- A Vercel project. If you don't have one, you can create a new project.
- The Vercel CLI installed. If you don't have it, you can install it using the following command:

Terminal

```
pnpm i -g vercel
```

1 Enable Speed Insights in Vercel

On the Vercel dashboard, select your Project followed by **Speed Insights** in the sidebar. You can also select the button below to be taken there. Then, select **Enable** from the dialog.

Go to Speed Insights

Enabling Speed Insights will add new routes (scoped at `/_vercel/speed-insights/*`) after your next deployment.

2 Add `@vercel/speed-insights` to your project

Using the package manager of your choice, add the `@vercel/speed-insights` package to your project:

Terminal

```
pnpm i @vercel/speed-insights
```

3 Add the `SpeedInsights` component to your app

The `SpeedInsights` component is a wrapper around the tracking script, offering more seamless integration with Next.js.

Add the following component to the root layout:

Next.js v13.5+ | Older Next.js versions

Add the following component to your main app file:

app/layout.tsx Next.js (/app) TypeScript

```
import { SpeedInsights } from '@vercel/speed-insights/next';

export default function RootLayout({
  children,
}: {
  children: React.ReactNode;
}) {
  return (
    <html lang="en">
      <head>
        <title>Next.js</title>
      </head>
      <body>
        {children}
        <SpeedInsights />
      </body>
    </html>
  );
}
```

4 Deploy your app to Vercel

You can deploy your app to Vercel's global CDN by running the following command from your terminal:

>_ terminal

```
vercel deploy
```

Alternatively, you can connect your project's git repository, which will enable Vercel to deploy your latest pushes and merges to main.

Once your app is deployed, it's ready to begin tracking performance metrics.

> If everything is set up correctly, you should be able to find the `/_vercel/speed-insights/script.js` script inside the body tag of your page.

5 View your data in the dashboard

Once your app is deployed, and users have visited your site, you can view the data in the dashboard.

To do so, go to your **dashboard**, select your project, and click **Speed Insights** in the sidebar.

After a few days of visitors, you'll be able to start exploring your metrics. For more information on how to use Speed Insights, see Using Speed Insights.
